Summary of effects of

Scalar Field Therapi on ADHD Symptoms

Pilotstudy conducted at

Quantum Healing Center København

2024-2025

🔬 Primary conclusions

1. **Measurable and clinically relevant effects**
   - Three 2-hour sessions with scalar field therapy (EES) resulted in **significant improvements** in ADHD symptoms as measured by both a questionnaire (ASRS) and an objective computer test (CPT3).
   - In particular, symptoms such as **inattention, hyperactivity, and impulsivity** were reduced.
2. **Sustained and growing effect**
   - The improvements continued for **several weeks after the last treatment**, without further sessions. This suggests a possible **long-term effect**, which may be due to the body's own self-healing response.
3. **Objective data supports the effect**
   - The CPT3 computer test showed improvements in attention and impulse control, which **cannot easily be explained by placebo** – unlike questionnaires.
4. **Subjective improvements**
   - 14 out of 19 participants reported improvements in ADHD-related areas: e.g., better concentration, more calmness, fever panic thoughts, and better self-regulation.
   - Many reported **positive effects outside of ADHD**, e.g., improved sleep, more energy, fewer menstrual symptoms, migraine relief, and emotional balance.
5. **Safety and side effects**
   - Only a few mild side effects were reported (e.g., headache, detox symptoms, fatigue), which were **temporary and did not require treatment**.

⚠️ Reservations and limitations

- **No control group**: The study was an open pilot study without a placebo or control group. This means that **placebo effects cannot be ruled out** – especially for the subjective assessments.
- **Low number of participants**: Only 16 of 19 completed the entire program – and although the results were statistically significant, they should be **validated in larger and more controlled studies**.
- **Non-diagnostic**: Participants had previously been diagnosed with ADHD/ADD, but the diagnosis was not clinically validated as part of the study.

✅ What does this mean for you if you are considering an EES session?

- The study indicates that **EES-based scalar field therapy has the potential to provide market improvements in ADHD symptoms** – and perhaps also in other mental and physical imbalances.
- The therapy appears to be **gentle and to have few side effects**, and the subjective experience for most participants was **positive and calming**.
- If you are looking for a **non-medical, energetic supplement to ADHD management or general self-healing**, scalar field therapy may be worth a try – especially in a safe and professional environment such as that described in the study.

📊 Key figures from the study

🔹 **Total number of participants:**

- **19 adults** diagnosed with ADHD or ADD
- **16 people** had sufficient data to be included in the statistical analysis

---

✅ Number who experienced positive effects on ADHD symptoms (self-reported)

- **14 out of 19 participants**
- **= ≈ 74%**
- Reported subjective improvements such as:
- → better concentration, inner calm, fewer panic thoughts, better sleep, less racing thoughts, better stress management, etc.

📉 Objectively measured improvements

🧠 ASRS questionnaire (subjective assessment in numerical form)

- **Significant reduction in ADHD symptoms in the majority of participants**→ Average improvement of:
  - **-26.7%** in A scores (from 17.2 to 12.6)
  - -25.6% in B scores (from 32.8 to 24.4)
  - **-27.4%** in inattention
  - **-60.0%** in motor hyperactivity/impulsivity
  - **-41.9%** in verbal hyperactivity/impulsivity
  - (Comparison between before (visit 1) and 6 weeks after last treatment)

💻 CPT3 computer test (objective neurocognitive test):

- **Detectability** (ability to distinguish relevant stimuli): improved in **the majority**, **significant**
- **Omissions** (lack of responses): **significant improvement**
- **Additions** (incorrect responses): **tendency toward improvement**, not significant

➡️ **Important note:** These results are **considered not to be attributable to placebo**, as CPT3 is an objective test.

🧘 Improvements outside ADHD (reported by participants)

- **Several people** also reported:
  - Less menstrual symptoms
  - Reduced migraines
  - Better sleep and more energy
  - Better emotional balance
  - Healing of old physical traumas (e.g., back, lower back, tailbone)

⚠️ Side effects (reported by 8 out of 19 participants)

- Mild headache
- Detox reactions (thirst, restlessness, heart palpitations)
- Short-term physical sensations (pressure, warmth, buzzing)
- Side effects were mild and transient, and none required treatment.

📜 Overall summary of data

Parameter	Result
Number of participants	19 individuals
Contributed with data	16 individuals
Rapporting of positiv effect	14 individuals (**74%**)
Objektive measurable effects (CPT3)	Majority, in particular on omissions
Significant drop in ADHD-score (ASRS)	Yes – for all key parameters
Side effects	8 individuals (**42%**) – mild and transient
